India Airfare Intelligence

Real-Time Airfare Price Index & CPI Augmentation Platform

"Collect → Clean → Measure → Explain → Validate → Predict → Augment"

A statistical intelligence platform for India's domestic aviation market – not a flight-booking site.

Prepared for a 5-minute stage presentation.

1. The Problem We're Solving

The SIH problem statement asks for an end-to-end platform that can **automatically collect airfare observations from airline and OTA sources, clean and normalise them, construct a representative Airfare Price Index, visualise price trends, and expose the results through an API** — with route weights informed by DGCA passenger-traffic data, multiple advance-purchase windows, and at least 30 days of back-testing against publicly available DGCA fare data.

The core technical question: how can millions of dynamic, messy airfare observations be converted into a reliable, representative, and explainable statistical measure of airfare inflation in India?

That splits into five real engineering challenges — and our product addresses all five in one integrated system:

1. **Data acquisition** — collecting fares continuously, ethically, from real sources
2. **Data quality & normalisation** — messy, multi-source, multi-currency-component data made comparable
3. **Statistical index construction** — a defensible, reproducible index, not a spreadsheet average
4. **Intelligence & interpretation** — explaining movements, not just plotting them
5. **Validation & policy application** — proving the number is right, and making it usable by a regulator

The positioning that matters in the room

Don't say: "MoSPI doesn't collect online airfare data." (It's not true — MoSPI's CPI 2024 series, base 2024=100, already incorporates alternative/digital data sources.)

Say instead: "We propose a scalable, high-frequency airfare intelligence architecture that continuously collects, normalises, validates and analyses online airfare observations, constructs a transparent route-weighted Airfare Price Index, detects abnormal price movements, validates itself against a real official benchmark, and demonstrates how high-frequency airfare information can *augment* official statistical analysis."

2. What We Built — the MVP, Module by Module

2.1 Data Acquisition Layer

Live fare collection through **SerpApi's Google Flights engine** — an authorised, ToS-compliant aggregator API, not a scraper. This was a deliberate pivot: we verified via `robots.txt` checks that direct scraping of EaseMyTrip and SpiceJet is explicitly disallowed, and chose the legitimate path instead of undermining our own credibility as a government-facing tool. The architecture still carries a full ethical-scraping safeguard layer (robots-guard, rate limiter, circuit breaker, challenge detector) for any future direct-adaptor sources.

2.2 The Index Engine

- **Laspeyres-style fixed-weight aggregation** across 15 DGCA-calibrated routes (weights sum to 1.0, renormalised over whichever routes are actually observed in a period — an exclusion is recorded, never silently dropped)
- **Trimmed-mean estimator** per route, per period, with a minimum-observation floor — a route-period below the floor is excluded rather than reported noisy
- **Two parallel series, not one: Core APIx** (base fare only) and **Headline APIx** (total fare, taxes and fees included) — the same validated engine, fed two different fare columns. This is the direct answer to the problem statement's demand to separate base fare / taxes / UDF / airport charges / convenience fee.
- Five advance-purchase windows modelled as a lead-time curve (T-45, T-30, T-15, T-7, T-1)

2.3 Validation — Proving the Number Is Right

Back-tested against the **real MoSPI e-Sankhyiki Airfare CPI** (item 07.3.3.1.2.01, base year 2024=100) — genuine government data, ingested directly from an official download, not simulated. Two series on different bases can't be honestly overlaid without reconciling scale, so we built an explicit, disclosed rebasing step: splice at the one real month both series share, publish the anchor month and scale factor alongside every result. Nothing is invented — the only "interpolation" is a straight line drawn between two real monthly points.

2.4 RBI Policy & Elasticity Simulator

- Core vs Headline toggle chart with reference bands at **+4% and +6%** — deliberately mirroring RBI's own real, statutory Flexible Inflation Targeting mandate (4% CPI target, 2%–6% tolerance band, under the RBI Act as amended in 2016)
- Price breakdown card: average base fare vs taxes & fees vs total, computed live from the day's actual observations
- Real-time **week-over-week inflation alert**: fires on a national Core APIx WoW move >6%, or any single route spiking >20% WoW — whichever is more severe drives the banner
- One-click **"Generate RBI Policy Brief"** CSV report, assembled from the exact same numbers the live dashboard shows

2.5 Reports, API & Governance

- Authenticated, documented REST API (OpenAPI docs) — built for "NSO/RBI-style" programmatic consumers, not just a UI
- Five CSV report templates: Weekly Index Summary, Route Intelligence Brief, Backtesting Validation, CPI Scenario Note, RBI Policy Brief
- **Row-Level Security enforced at the database**, not just the API — a missing role setting fails closed, not open
- Every response carries a `data_mode` flag — the platform never silently claims "live" when it's actually replayed/demo data

Stack: Next.js 14 + TypeScript + ECharts (frontend) · FastAPI + SQLAlchemy 2.0 async (backend) · PostgreSQL 16 + TimescaleDB with RLS · Redis + Celery · Docker Compose (portable, offline-capable) / Supabase (shared team DB).

3. Proof It Works — Real Numbers, Not a Mockup

Everything below is a live, computed result verified against the running system today — no fabricated figures.

2,637 REAL FLIGHT QUOTES COLLECTED (2 LIVE SERPAPI RUNS)	15 DGCA-WEIGHTED ROUTES TRACKED	117.3 TODAY'S NATIONAL AIRFARE INDEX	35 days AHEAD OF THE LATEST OFFICIAL MOSPI RELEASE
--	---	--	--

Core vs Headline — a genuinely new signal

On the same day (Sep 3, 2026): **Core APIx = 121.2** (base fare only) vs **Headline APIx = 117.7** (total fare). Two different, real numbers — proof the split is measuring something, not just relabelling one series twice. A base-fare-only signal is exactly what an RBI-style user would want when a government levy or fee changes and they need to know if the **airline** moved price, or the **tax** did.

Real independent validation, not a synthetic backtest

METRIC	VALUE	WHY IT'S CREDIBLE
Real overlapping months (vs MoSPI CPI)	7	Genuine government data, not simulated
Correlation	0.7389	A believable, moderate number — not a suspicious 0.99+
MAPE	12.3%	Disclosed openly, not hidden
Rebase anchor / scale factor	Jan 2026 / 1.2153	Published alongside every result — nothing hidden

The alert system catching something real

On real live data: **BLR-HYD spiked +49.2% week-over-week** in base fare — well past the 20% route-spike threshold — and the system correctly fired `HIGH_INFLATION_RISK` with a route-specific message, even while the **national** number stayed within its own band. That's the alert logic correctly distinguishing a localised shock from a systemic one — on data we didn't script.

Today's live run

75/75 SerpApi queries succeeded, 1,482 real flight quotes, processed through the full pipeline (0 rejected, 82 outliers correctly flagged by the trimmed-mean estimator), national index computed end-to-end: **117.304**.

4. Manual Methods vs India Airfare Intelligence

DIMENSION	TRADITIONAL / MANUAL APPROACH	INDIA AIRFARE INTELLIGENCE
Frequency	Monthly CPI release cycle	Daily nowcast — 35 days ahead of the latest official release
Granularity	One blended national "Airfare" line item	Route-level + regional + national, Core vs Headline, 5 lead-time windows
Fare decomposition	Not available — quoted total only	Base fare / taxes / UDF / airport charges / convenience fee, fully split
Anomaly detection	Discovered after the fact, if at all	Automated WoW + route-spike alerting, in real time
Transparency	Methodology and weights not publicly reproducible	Open methodology page, disclosed weights, disclosed rebasing math, per-observation quality scores
External validation	Largely unfalsifiable by an outsider	Backtested against real MoSPI CPI, error metrics published (MAE/RMSE/MAPE/correlation)
Scalability	Expensive to extend — more routes = more manual effort	Software-only marginal cost; add a route by adding a weight row
Auditability	No accessible audit trail	Row-Level Security, quality-scored per observation, full Data Explorer

5. Understanding the Ecosystem

MoSPI — Ministry of Statistics and Programme Implementation

The central government ministry responsible for India's official statistics — national accounts, price indices, large-scale socio-economic surveys. It sets the statistical policy and standards that the rest of the system relies on.

NSO — National Statistical Office

The operational/implementing arm under MoSPI. It runs the actual field machinery: designated price-collection centres, the Household Consumption Expenditure Survey (HCES) that derives CPI basket weights, and monthly computation and release of the CPI via the e-Sankhyiki portal. The current CPI 2024 series (base year 2024=100, weights from HCES 2023-24, COICOP 2018 classification) already includes an item-level "Airfare" sub-index within Transport & Communication — this is the exact real series our platform validates against.

RBI — Reserve Bank of India

India's central bank. Under its Flexible Inflation Targeting mandate (RBI Act, as amended in 2016), the Monetary Policy Committee targets CPI inflation at **4%, with a tolerance band of 2%–6%** — this is the exact structural framework our platform's own policy bands (+4% / +6%) are built around. RBI is a downstream *consumer* of MoSPI's CPI — it only sees the number with MoSPI's publication lag. A high-frequency, item-level nowcast is directly useful to exactly this kind of consumer.

DGCA — Directorate General of Civil Aviation

India's civil aviation regulator, under the Ministry of Civil Aviation. Oversees airline licensing, safety, and operational compliance, and publishes periodic domestic air-traffic and passenger statistics. Its passenger-traffic data is what the problem statement asks route weights to be calibrated against — which is exactly how this platform's 15-route basket weights were derived.

The pitch-worthy insight: none of these four organisations currently talks to each other on airfare specifically at high frequency. MoSPI measures it monthly and broadly; DGCA regulates and reports traffic; RBI consumes CPI with a lag it cannot shorten on its own. This platform is the connective, high-frequency layer none of them currently has.

6. The Journey — Problems We Faced, and How We Solved Them

"Automated collection... ethically" (PS requirement)

Problem: our first instinct was direct browser automation against OTA sites. Real robots.txt checks showed EaseMyTrip and SpiceJet both explicitly disallow it.

Solution: pivoted to SerpApi's Google Flights engine — a legitimate, authorised API — rather than compromise the platform's own credibility as a trustworthy, government-facing statistical tool. The ethical-collection safeguard layer we'd already built (robots-guard, rate limiter, circuit breaker) stayed in the architecture for future direct sources.

"Separate base fare / taxes / UDF / charges" (PS requirement)

Problem: a single blended fare number can't tell a regulator whether an airline moved price or a tax did.

Solution: built a full second index series (Core APIx, base-fare-only) alongside the existing Headline series, reusing the identical validated engine — verified live to produce genuinely different numbers on the same day (121.2 vs 117.7).

"Back-test against DGCA data" (PS requirement) — the honesty problem

Problem: the project's existing back-test benchmark turned out to be synthetic — generated by adding noise to our own index, not from an independent source. We found this, and chose to flag it rather than let a fabricated 0.99+ correlation stand unchallenged in front of judges.

Solution: ingested the real MoSPI e-Sankhyiki Airfare CPI and built a genuinely independent validation instead — a believable 0.74 correlation, openly disclosed, is a stronger credibility story than a suspiciously perfect fake one.

Reconciling two different statistical bases, honestly

Problem: our index (base Sept 2025 = 100) and MoSPI's CPI (base year 2024 = 100) are not on the same scale — overlaying them directly would misrepresent the comparison.

Solution: a disclosed splice/rebase at the one real overlapping month, with the anchor month and scale factor always published alongside the result — a standard statistical technique, applied transparently rather than hidden.

Turning "we're faster" into a number

Problem: "real-time" is a claim anyone can make.

Solution: computed it — MoSPI's latest release (July 2026) is 35 days old as of today; our nowcast already reaches September. That's not a marketing line, it's today – `end_of(last_official_month)`, recomputed live every time the page loads.

Real engineering discipline along the way

- Seven distinct CI failures, each root-caused with real log evidence rather than guessed at (a missing dependency, an RLS bypass in the test database role, an async test-loop scoping bug,

and more)

- A stale duplicate backend process silently serving pre-live data — caught via netstat, not assumed away
- A date-window mismatch that would have broken the Core/Headline toggle's shared x-axis — caught and fixed before it ever reached the UI

7. The 5-Minute Pitch (Speak This)

0:00-0:40 — OPEN WITH THE GAP

"India's domestic airfare market moves every day — by route, by booking window, by season, by festival. But the only official measurement of it, the MoSPI Consumer Price Index, is monthly, broad, and lagged. As of today, the most recent official airfare CPI figure is for July — a month and a half old. RBI's Monetary Policy Committee, DGCA, and every economist who cares about this number is working with information that's already stale by the time they see it."

0:40-1:40 — WHAT WE BUILT

"We built India Airfare Intelligence: a platform that collects real fare data daily across 15 DGCA-weighted routes, splits every fare into base price and taxes — not just one blended number — and computes two parallel indices: a Core index that tracks what airlines actually charge, and a Headline index that tracks what consumers actually pay. On the same day, those two numbers are already different — 121.2 versus 117.7 — which is exactly the kind of signal a tax change would hide in a single blended number, but our platform exposes it."

1:40-2:40 — PROVE IT'S REAL, NOT A DEMO

"This isn't a mockup. We collected 2,637 real flight quotes through an authorised aggregator API in the last two days alone. And critically — we didn't just build our own index and call it validated. We went and got the real, official MoSPI Airfare CPI, and back-tested our number against it, honestly. Two series on different statistical bases can't just be overlaid — so we built a transparent rebasing method, disclosed the exact anchor point and scale factor we used, and got a real correlation of 0.74. Not a suspiciously perfect number — a believable one, because it's genuine."

2:40-3:40 — THE ALERT SYSTEM, LIVE

"We built a real-time inflation alert, modelled directly on RBI's own actual policy framework — the 4% target, 2-to-6% tolerance band that's been law since 2016. On real data, this system caught something real: one route, Bangalore-Hyderabad, spiked 49% week-over-week in base fare. Our system correctly flagged it as a localised route shock, not a systemic national one — because the national number itself stayed calm. That's the difference between a chart and intelligence."

3:40-4:30 — WHY THIS MATTERS TO THE ECOSYSTEM

"MoSPI measures broadly and monthly. DGCA regulates and reports traffic. RBI consumes CPI with a lag it can't shorten on its own. Nobody currently sits between them with a high-frequency, item-level, honestly-validated airfare signal. That's the layer we built — and today, it's already 35 days ahead of the last official release."

4:30-5:00 — CLOSE

"We didn't just build a dashboard. We built a statistically defensible, independently validated, real-time augmentation layer for exactly the gap the problem statement described — and we can show you it running, live, right now."

8. Key Things to Highlight (and Likely Questions)

Lead with these, in order

1. The Core vs Headline split — nobody else separates base fare from tax in a live index
2. The real MoSPI validation — and that we chose honesty over a fake 0.99 correlation
3. The 35-day nowcast lead, computed live, not asserted
4. The RBI-framework-native alert bands (4%/6%) — this wasn't arbitrary, it's their real mandate
5. 2,637 real flight quotes, two live collection runs, today — not seeded/fake for the demo

If asked "is this scraping / is this legal?"

No direct scraping of OTA sites. We use SerpApi's Google Flights engine, an authorised third-party API — verified the ToS position via real robots.txt checks before deciding, and chose the compliant path.

If asked "how do you know your index is correct?"

Back-tested against the real MoSPI e-Sankhyiki Airfare CPI (not a synthetic benchmark), with a fully disclosed rebasing methodology and openly published error metrics — correlation, MAE, RMSE, MAPE.

If asked "why should RBI/MoSPI care about this instead of just waiting for their own release?"

Frequency and granularity: they get one national number a month; we give route-level, lead-time-level, Core/Headline-decomposed signal daily — positioned explicitly as an *augmentation* layer, not a replacement or a claim that official data collection is deficient.

If asked "what's not done yet / what would you build next?"

Two explicitly deferred items, by design: an ATF fuel-tax pass-through slider (needs a validated economic assumption before it ships) and a lead-time-reweighted index toggle (a methodology change that needs re-validation before exposing it as a live control). Both are logged as deliberate scope decisions, not oversights.

This document was assembled from the project's own implementation logs and live-verified figures as of the date of generation. Every statistic above was read directly from the running system, not recalled from memory.
